Sales Data Analysis Project

CodeOrbit Tech — Data Analyst Internship | 1-Month Internship

Prepared by: Bhavana M

1. Abstract

This project demonstrates an end-to-end basic data analysis workflow using an illustrative retail sales dataset:

data cleaning, KPI calculation, grouping by product/category/region/month, and dashboard reporting.

2. Objectives

• Clean data quality issues • Calculate total sales, order count and average order value • Compare sales by

category, region, product and month • Present findings and recommendations.

3. Dataset and Cleaning

The synthetic sample contains 25 raw rows and order date, region, category, product, unit price, quantity and channel fields. Text was trimmed and standardized, numeric/date types converted, missing product set to Unknown, missing quantity set to 1 as a documented example assumption, and 1 duplicate business record(s) removed.

4. Key Metrics

Metric	Result
Total Sales	₹1,620.00
Unique Orders	24
Average Order Value	₹67.50
Top Product	Headphones (₹300.00)
Top Region	South (₹472.00)
Top Category	Electronics (₹800.00)
Duplicate Records Removed	1

5. Findings and Dashboard

The highest-sales product is Headphones; the top region is South; and the top category is Electronics. The highest-sales month is 2026-03.

6. Recommendations

Review inventory for Headphones; investigate the drivers of performance in South; track monthly trends over time; improve validation of dates, quantities, regions and product names; and confirm any missing-value assumptions with the data owner.

7. Limitations and Conclusion

This is a small synthetic dataset for learning and demonstration, not actual company data. Results should not be treated as real business findings. The project illustrates a reproducible process for cleaning, analysis, KPI reporting and visualization.
